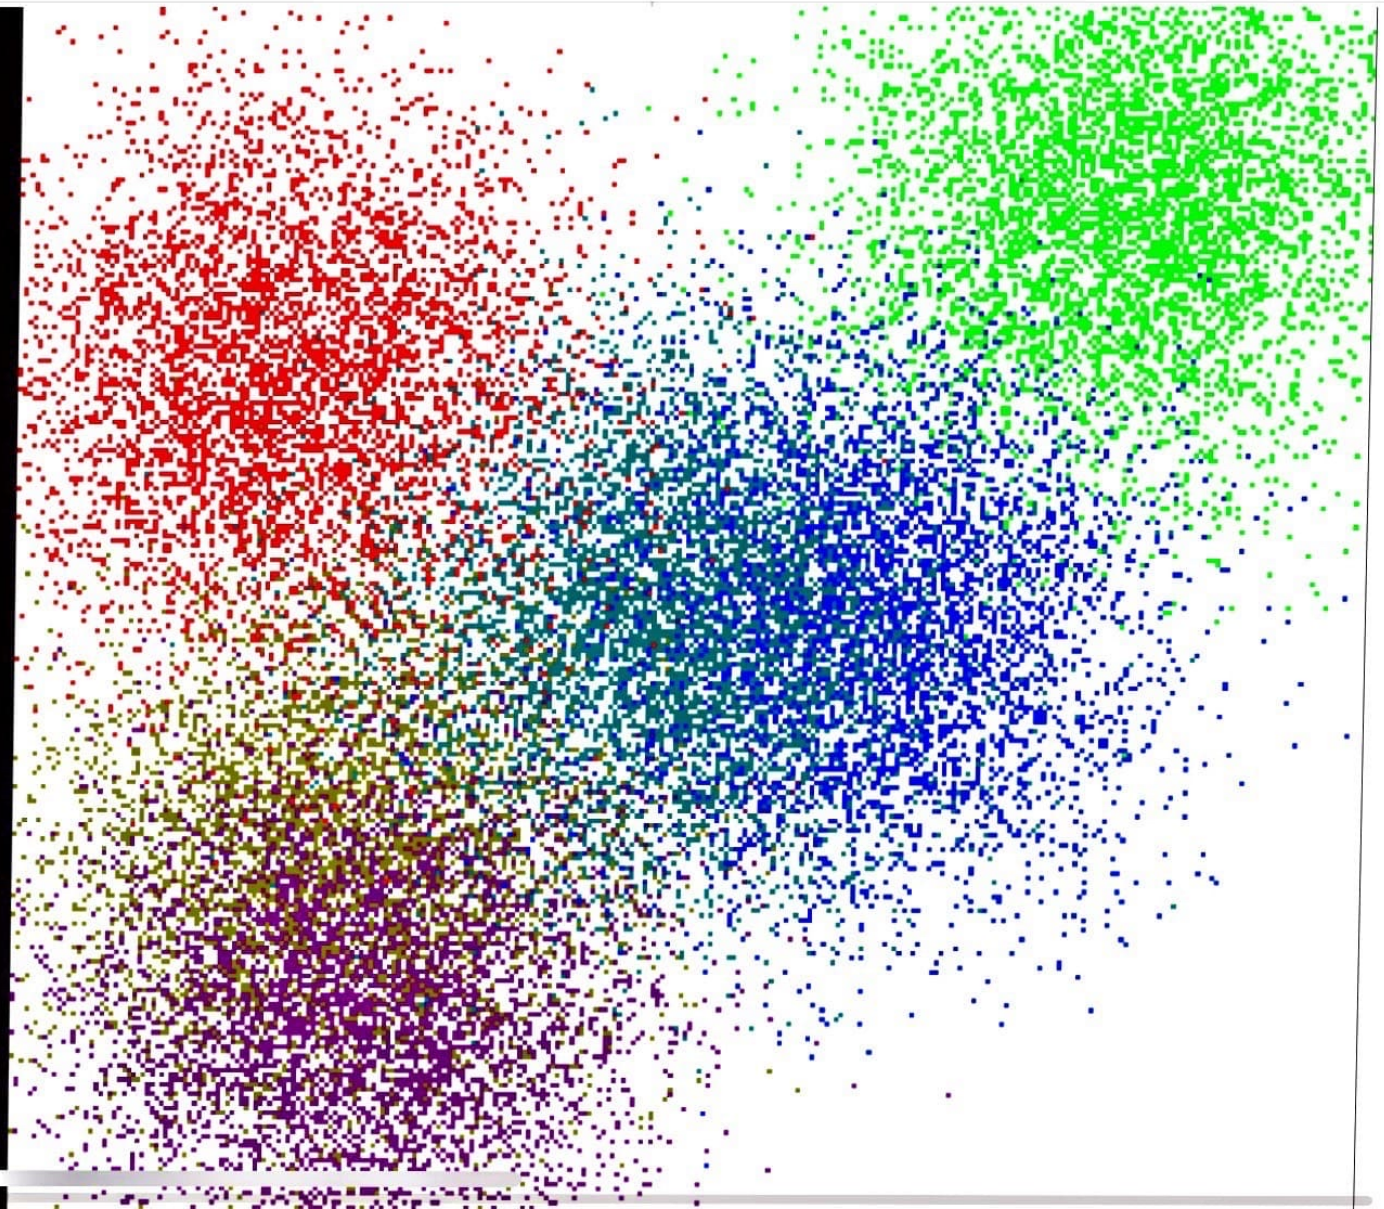
Data Mining : Clustering



What is clustering?

Cluster Analysis ("data segmentation") is an exploratory method for identifying homogenous groups ("clusters") of records

Similar records should belong to the same cluster

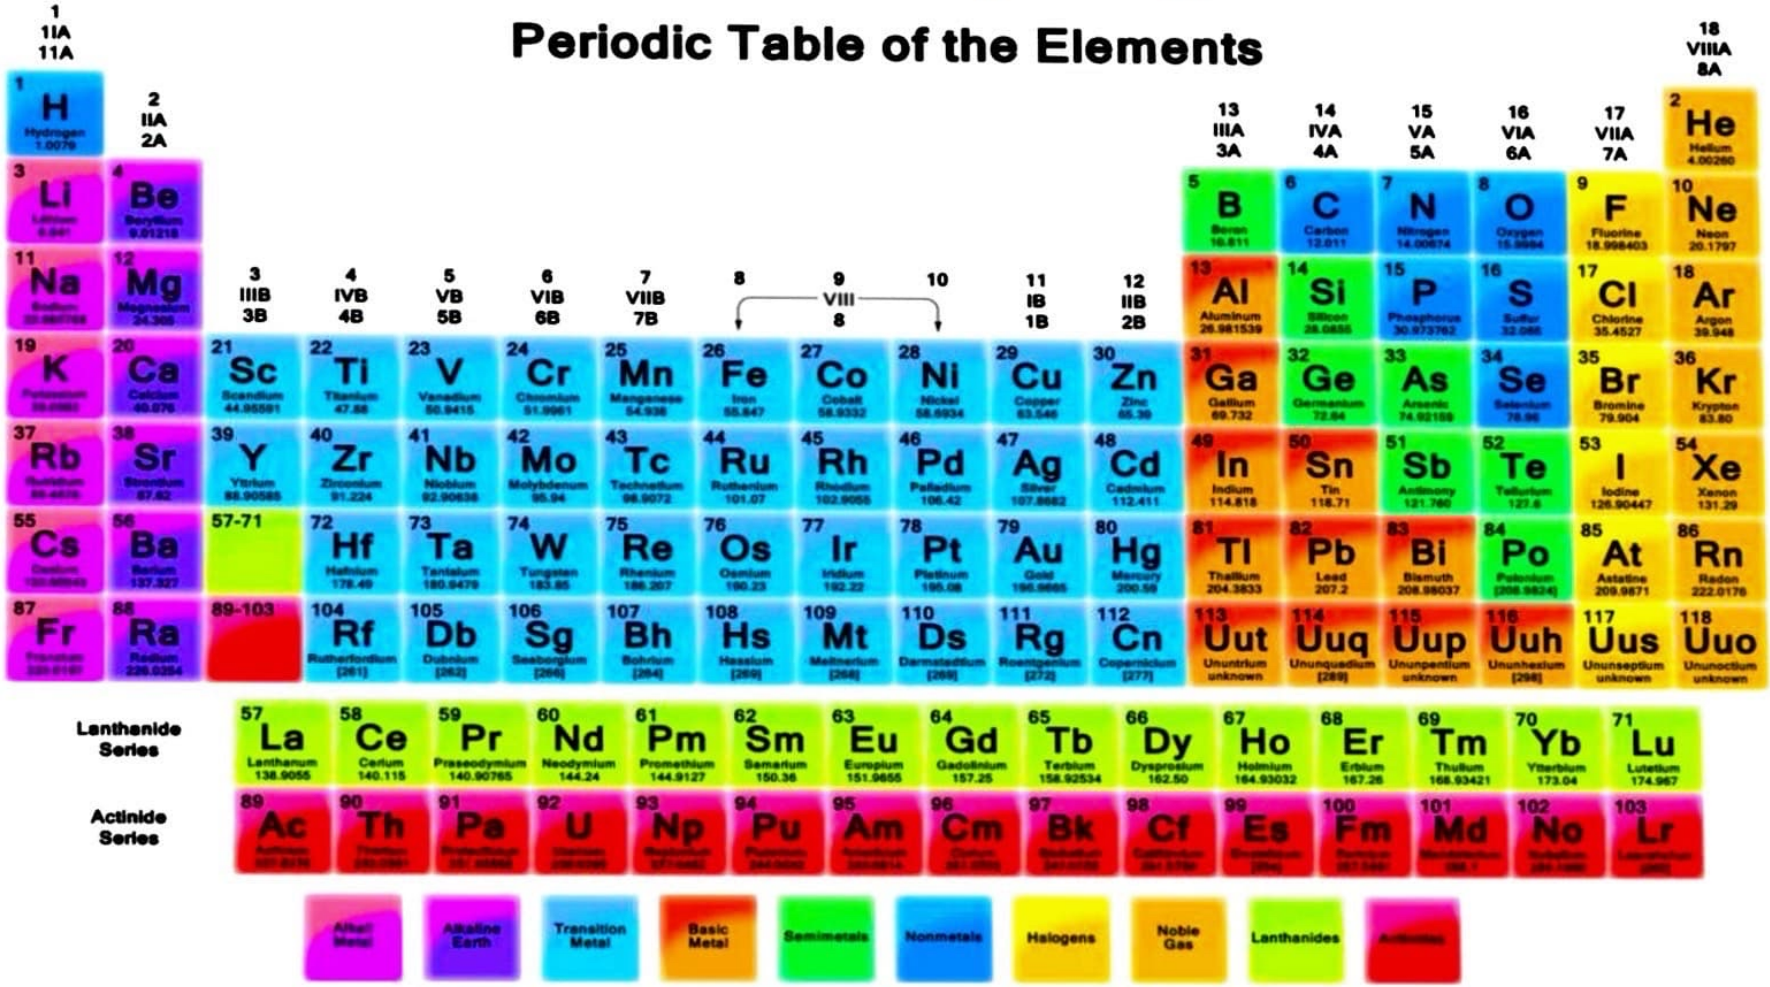
Dissimilar records should belong to different clusters

So What and Why Clustering?

Clustering = Grouping "**Similar**" things together!

- **Understand/Discover** structure in data
- **Summarize** data points by their "**Cluster center**"

Nature is “naturally” organized



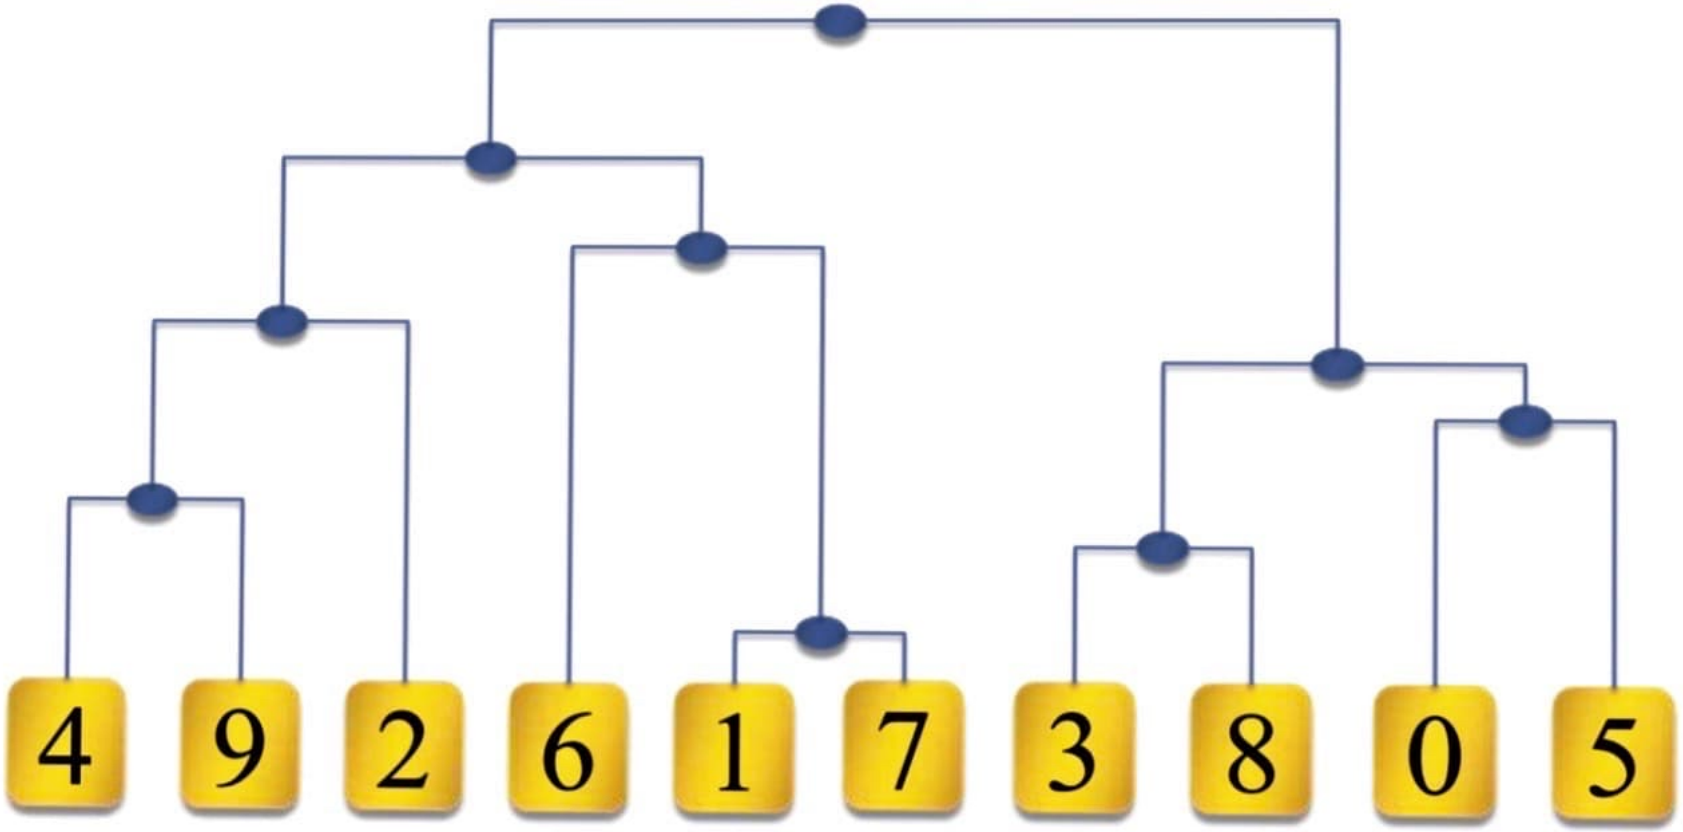
What Business questions can be answered?

- T*ypes* of **pages** are there on the **Web**?
- T*ypes* of **customers** are there in my **market**?
- T*ypes* of **people** are there on a **Social network**?
- T*ypes* of **E-mails** in my **Inbox**?
- T*ypes* of **Genes** the **human genome** has?

Hierarchical Clustering

Agglomerative Clustering

Hierarchical Clustering :Bottom-Up (Agglomerative)



- **SIMILARITY** between two **DATA POINTS**? **Sim**(0, 5)
- **SIMILARITY** between **CLUSTERS**? **Sim**({3, 8}, {0, 5})

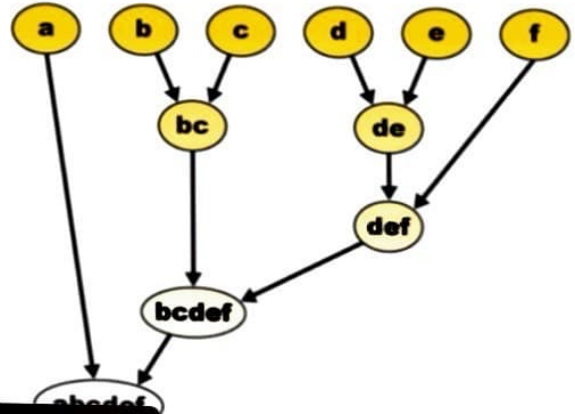
Hierarchical Clustering Algorithm

Start with *n* clusters (record = cluster)

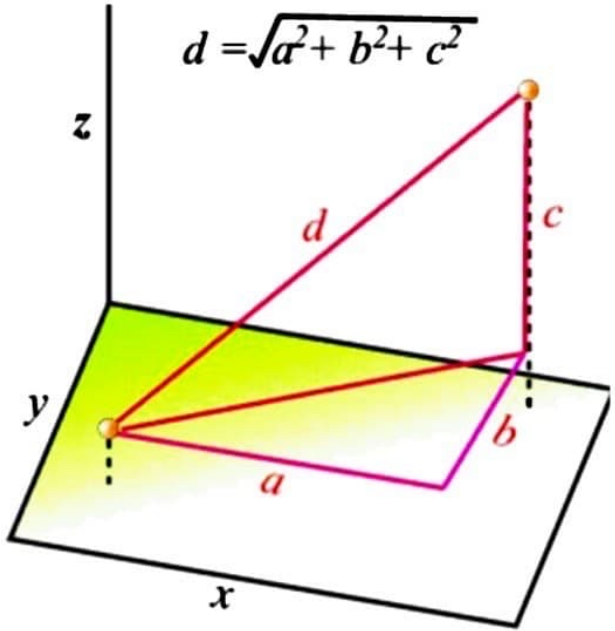
Step 1: two closest records are merged into one cluster

At every step, pair of clusters with *smallest distance* are merged (either single record added to existing cluster, or two existing clusters are combined)

Requires a definition of **distance**



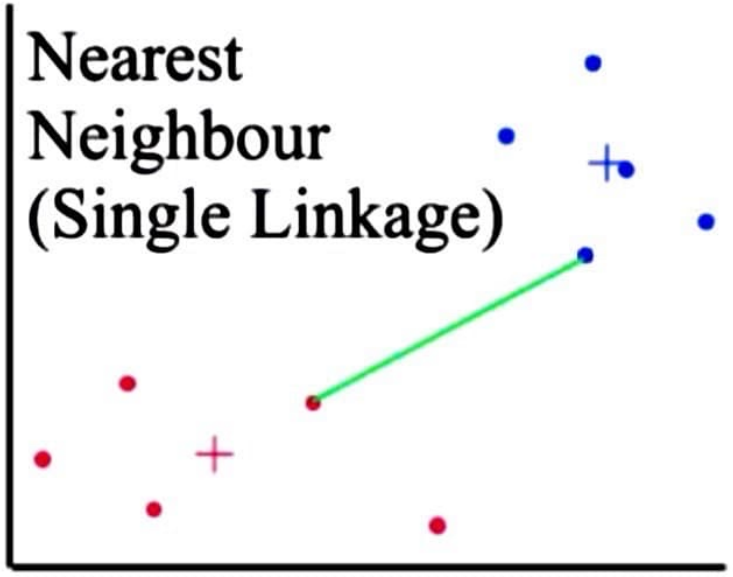
Euclidean Distance



$$d_{ij} = \sqrt{\left(x_{i1} - x_{j1}\right)^2 + \left(x_{i2} - x_{j2}\right)^2 + \cdots + \left(x_{ip} - x_{jp}\right)^2}$$

Distances Between Clusters: 'single linkage' ('nearest neighbor')

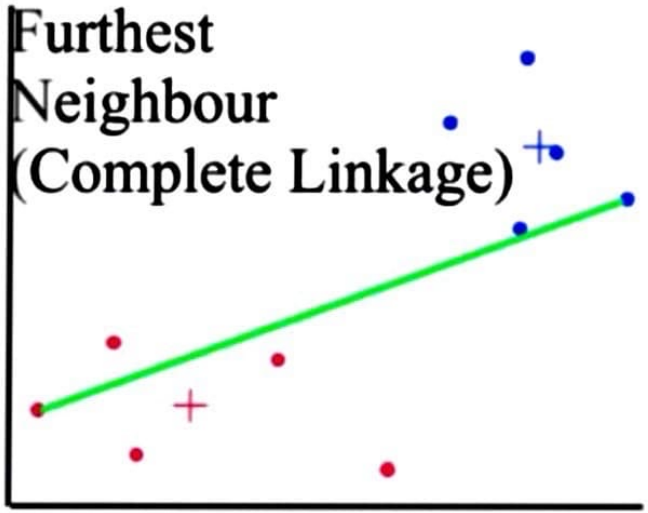
Distance between 2 clusters = **minimum distance** between members of the two clusters



$$\Delta\left(\mathbf{C}_{\alpha},\mathbf{C}_{\beta}\right)=\min_{\mathbf{x}\in\mathbf{C}_{\alpha},\mathbf{y}\in\mathbf{C}_{\beta}}\left\{\Delta\left(\mathbf{x},\mathbf{y}\right)\right\}$$

Distances Between Clusters: 'complete linkage' ('farthest neighbor')

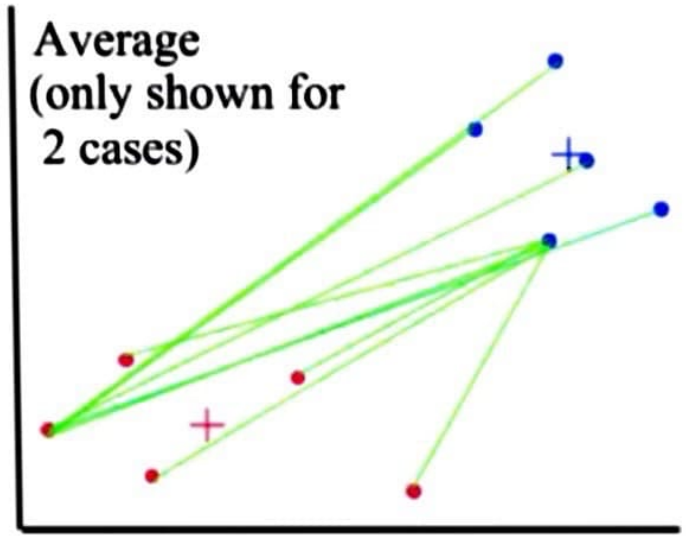
Distance between 2 clusters = **greatest distance** between members of the two clusters



$$\Delta\left(\mathbf{C}_{\alpha},\mathbf{C}_{\beta}\right)=\max_{\mathbf{x}\in\mathbf{C}_{\alpha},\mathbf{y}\in\mathbf{C}_{\beta}}\left\{\Delta\left(\mathbf{x},\mathbf{y}\right)\right\}$$

Distances Between Clusters: 'average linkage'

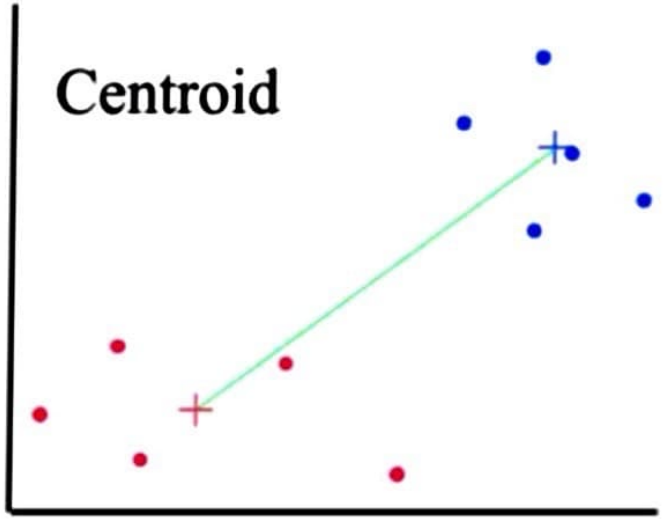
Distance between 2 clusters = **average** of all distances between members of the two clusters



$$\Delta\left(\mathbf{C}_{\alpha},\mathbf{C}_{\beta}\right)=\frac{1}{\left|\mathbf{C}_{\alpha}\right|\left|\mathbf{C}_{\beta}\right|}\sum_{\mathbf{x}\in\mathbf{C}_{\alpha}}\sum_{\mathbf{y}\in\mathbf{C}_{\beta}}\Delta\left(\mathbf{x},\mathbf{y}\right)$$

Distances Between Clusters: 'centroid linkage'

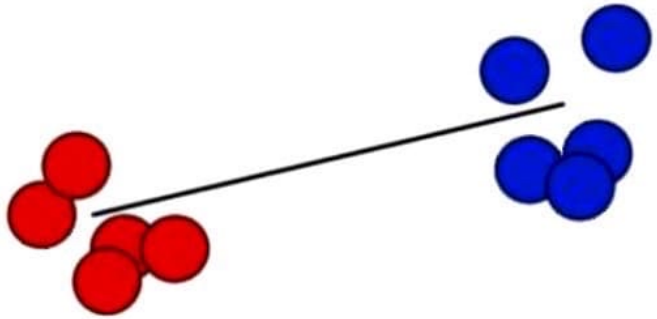
Distance between 2 clusters =
distance between their **centroids** (centers)



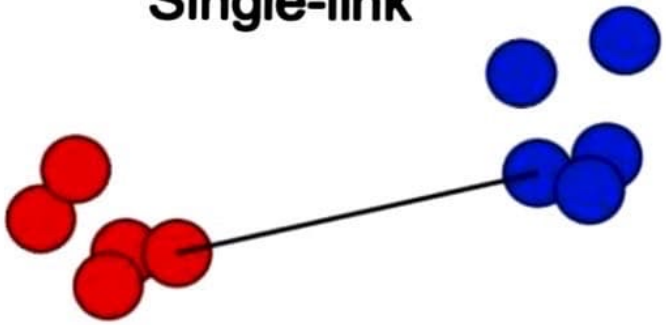
$$\Delta\left(\mathbf{C}_{\alpha},\mathbf{C}_{\beta}\right)=\left\|\mathbf{m}_{\alpha}-\mathbf{m}_{\beta}\right\|$$

All linkage methods

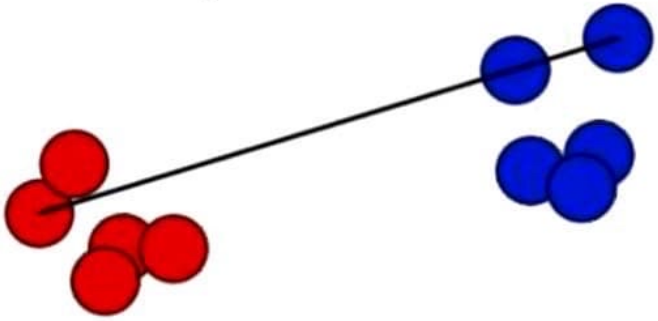
Distance between centroids



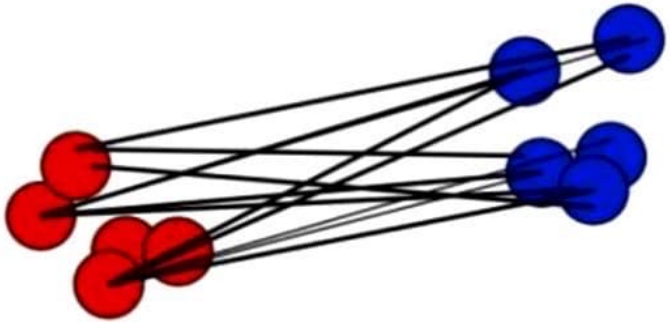
Single-link



Complete-link

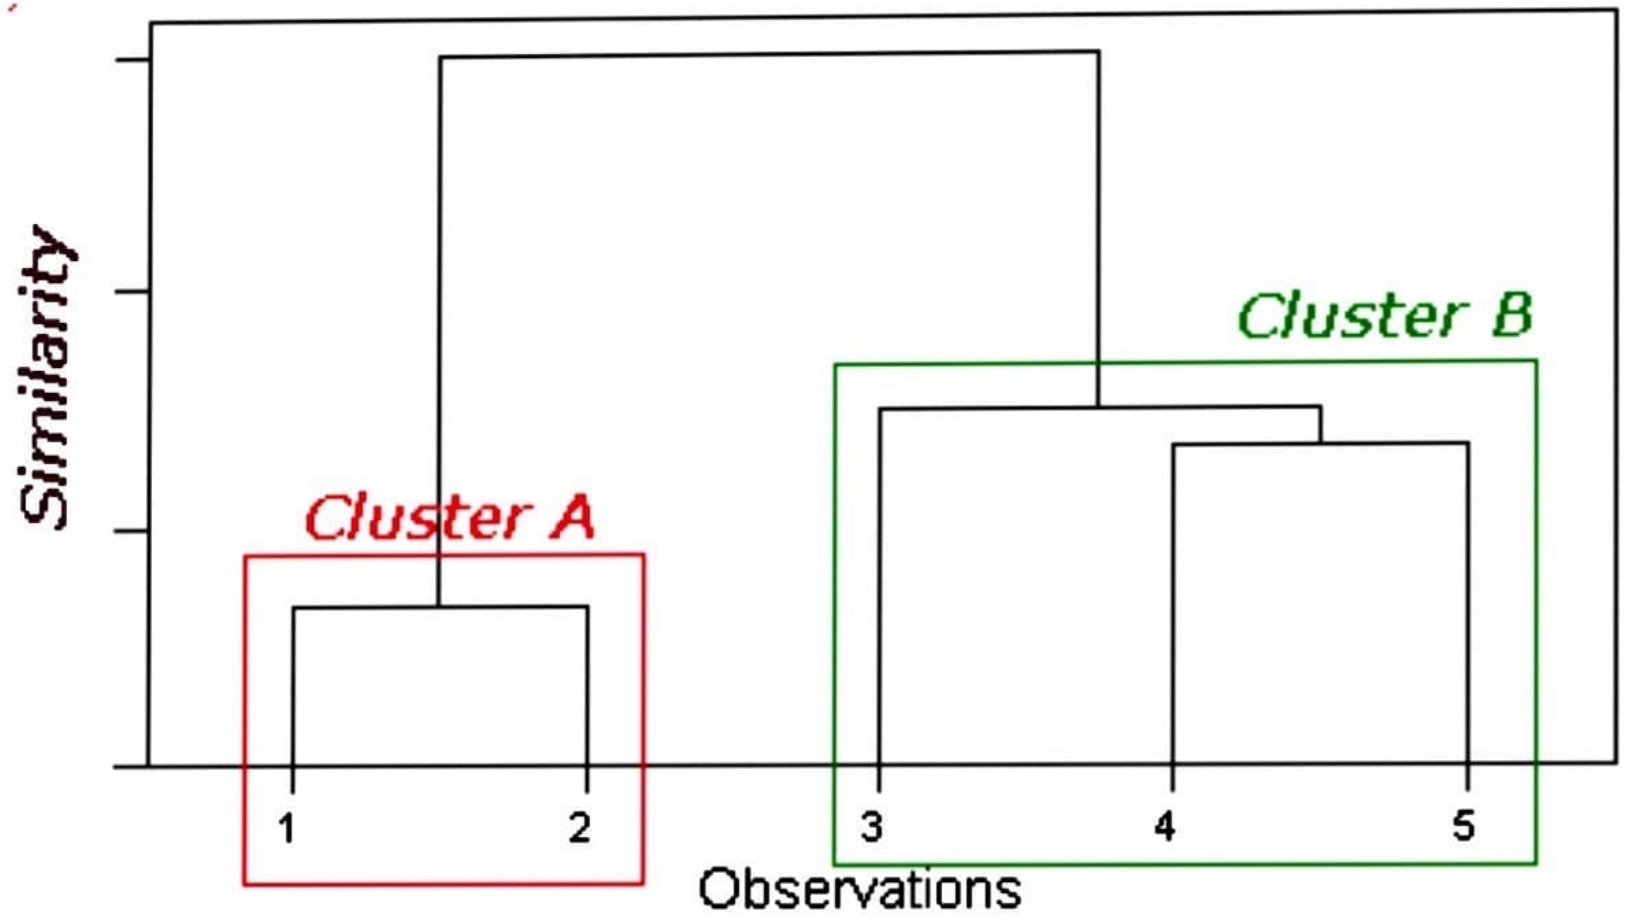


Mean-link



Let us work on simple example

Finally: Summarize process in a **Dendrogram**



University Data set

Data for 25 undergraduate programs at business schools in US universities in 1995.

This dataset excludes **image variables** (student satisfaction, employer satisfaction, deans' opinions)

Student quality | **Program** | **Placement**

Univ	SAT	Top10	Accept	SFRatio	Expenses	GradRate
Brown	1310	89	22	13	22,704	94
CalTech	1415	100	25	6	63,575	81

UVA	1225	77	44	14	13,349	92
UWisconsin	1085	40	69	15	11,857	71
Yale	1375	95	19	11	43,514	96

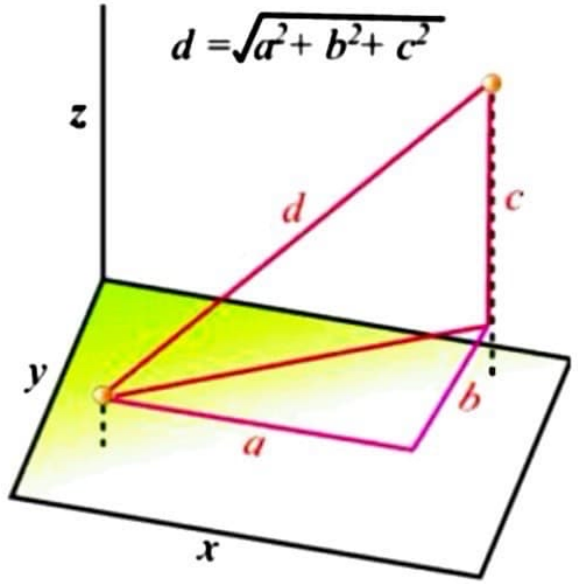
Notation: $x_i = (x_{i1}, x_{i2}, \ldots, x_{ip})$

$x_j = (x_{j1}, x_{j2}, \ldots, x_{jp})$

Caltech = (1415, 100, 25, 6, 63575, 81)

Cornell = (1280, 83, 33, 13, 21864, 90)

Euclidean Distance



$$d_{ij} = \sqrt{\left(x_{i1} - x_{j1}\right)^2 + \left(x_{i2} - x_{j2}\right)^2 + \cdots + \left(x_{ip} - x_{jp}\right)^2}$$

6-dimensional Euclidean distance between Caltech and Cornell:

$\sqrt{}$ [(1415-1280)^2 + (100-83)^2 + (25-33)^2 + (6-13)^2 +

+ (63575-21864)^2 + (81-90)^2] = 41,711.22

Standardize if multiple variables (p>1)

Euclidean distance is influenced by the **units** of the different measurements

Solution: standardize (=normalize) each variable before measuring distances

Standardizing: Example

$$Z\_SAT = \frac{SAT - mean(SAT)}{std(SAT)}$$

Univ	Z_SAT	Z_Top10	Z_Accept	Z_SFRatio	Z_Expenses	Z_GradRate
Brown	0.401994	0.644235	-0.871888	0.068840897	-0.32471667	0.80372917
CalTech	1.370988	1.210256	-0.719814	-1.65218153	2.508651168	-0.631501491
CMU	-0.059432	-0.74509	1.003685	-0.91460049	-0.16374483	-1.625122718
Columbia	0.401994	-0.024699	-0.770506	-0.17701945	0.285756214	0.141315019
Cornell	0.125139	0.335496	-0.314285	0.068840897	-0.38294938	0.362119736
Dartmouth	0.67885	0.644235	-0.821197	-0.66874014	0.330955887	0.914131529
Duke	0.448137	0.695691	-0.466359	-0.17701945	0.290955563	0.914131529
Georgetown	-0.105574	-0.127612	-0.770506	-0.17701945	-0.50343562	0.582924453

Euclidean distance between standardized Caltech and Cornell:

$$\sqrt{[\,(1.371-1.125)^2 + (1.210-0.335)^2 + \ldots + (-.632-.362)^2]} = 3.84$$

From Dendrograms to Clusters

- After dendrogram is obtained, **cut** it to create clusters. **How?**
- Examine *distance levels*
  - Cutpoint determines # clusters
  - Obtain statistics on resulting clusters
